The long-term impact of daily social exposure on the circadian rhythm of locomotor activity of young rats was evaluated under a 12 h light/12 h darkness photoperiod. A significant relationship was found between the aversiveness of the non-food stimulus and the pattern of activity response of the rats. The more 'aversive' the stimulus was, the more 'chaotic' the activity pattern was during the exposure. The effects were independent of the number of exposures (separate and in aggregate). The effects were not due to habituation, as: (i) the pattern of activity response was not different on the first exposure compared to the last and (ii) the pattern of activity response was different from the one seen in a separate group of rats in which the same procedures were not used for habituation. These results suggest that the brain reacts to social conditions by changing the circadian rhythm of activity, apparently due to the change in the pattern of the release of the endogenous, circadian, rhythm of hormone.// Copyright (c) 2018 Couchbase, Inc. // // Licensed under the Apache License, Version 2.0 (the
